

SEX LINKED TRAITS

Essential Questions:

What does “sex-linked” or “X-linked” mean?

How are sex-linked conditions inherited?

How do you solve sex-linked problems?

Sex-Linked Inheritance

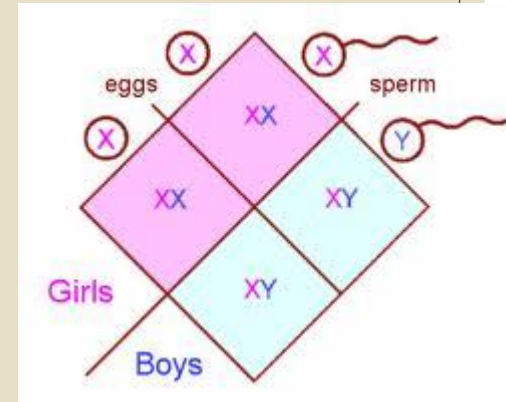

Comparison of the X and Y sex (23rd pair) chromosomes

- Sex linked inheritance varies the Mendel number of 3:1 by having males a **50/50** percent chance of inheriting the characteristic on the X chromosome only.
- Remember, Females have XX and Males are XY.
 - The Y carries little genetic information, mainly those that contribute to male characteristics. (*About 87 genes total.*)
 - The X carries a lot more genetic information. (*About 2000!*)

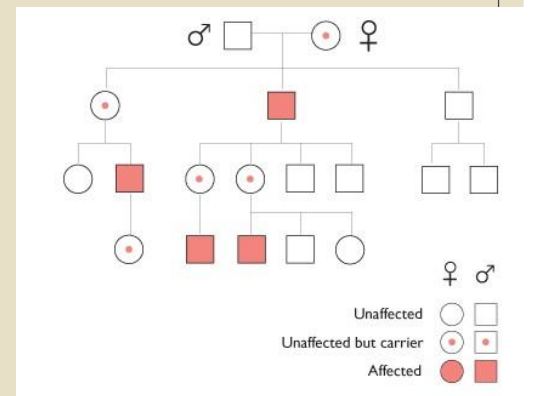

Who is affected by Sex-Linked Disorders?

- Genes for certain traits are on the **X chromosome only...**
 - Since **Men** only receive one X chromosome then they are **more likely** to inherit these types of disorders.
 - Who gives men the X Chromosome?
 - Women are somewhat protected since they receive two X chromosomes and are less likely to inherit these types of disorders.
 - What do you think happens when they get only one defective copy of an X chromosome?

Sex-Linked Disorders

- **Affected males never pass the disease to their sons** because there is no male-to-male transmission of the X chromosome.
- Affected males pass the defective X chromosome to **all of their daughters**, who are described as **carriers**.
 - This means they carry the disease-causing allele but generally show no disease symptoms since a functional copy of the gene is present on the other chromosome.
- Female carriers pass the defective X chromosome to...
 - **half their sons** (who are affected by the disease)
 - **half their daughters** (who are therefore also carriers).
 - The other children inherit the normal copy of the chromosome.
- **Affected females**, with two deficient X chromosomes, are the rare products of a marriage between an **affected male and a carrier (or affected) female**.

How do you solve Sex-linked Problems?

If Red eyes are dominant and sex-linked, show the cross between a homozygous red eyed female and a white eyed male.

		White-Eyed Male	
		X^r	Y
Red-Eyed Female	X^R	$X^R X^r$	$X^R Y$
	X^R	$X^R X^r$	$X^R Y$

1. You determine which trait (or disorder) is **dominant** or **recessive**.
2. Set up a punnett square using XX for females and XY for males.
 1. **Assign alleles for X only!**
3. Solve as usual, keeping in mind that the Y chromosome has **no allele!**

Genotypes: $X^R X^r$, $X^R Y$

Phenotypes: All offspring have red eyes.

Practice: Your Turn!

- Hemophilia is a sex-linked trait where X^H gives normal blood clotting and is dominant to the hemophilia allele X^h .
- Identify the genotypes of...
 - 1) a woman with normal blood clotting whose father had hemophilia
 - 2) a normal man whose father had hemophilia.
- What is the probability that a mating between these two individuals will produce a child, regardless of sex, that has hemophilia?

Check your work

- 1) the woman has normal clotting so she has one X^H but she got a X^h from her father, so she is $X^H X^h$
- 2) the man is $X^H Y$ since he got the Y from his father and he is normal so must be $X^H Y$

	X^H	X^h
X^H	$X^H X^H$	$X^H X^h$
Y	$X^H Y$	$X^h Y$

Genotypes: $\frac{1}{4} X^H X^H$
 $\frac{1}{4} X^H X^h$
 $\frac{1}{4} X^H Y$
 $\frac{1}{4} X^h Y$

Phenotypes: $\frac{1}{2}$ unaffected girls
 $\frac{1}{4}$ unaffected boy
 $\frac{1}{4}$ affected boy

Notice how girls are “protected” from disorders and carry them.
